1 Introduction

Write introductory paragraph here

1.1 Android application fundamentals

Android application are mostly written in Java. The Android SDK tool compile this code along with any data and resources files into an APK, an Android Package. One APK file contain all contents of an Android app and is the file that Android devices use to install the application [1]. We will discuss the structure of an APK file in section 1.2. In this section we will discuss some basic parts of an Android application.

1.1.1 Application components

The essential building blocks of an Android application are called App components. Each component is an entry point to the application. Each type serves a distinct purpose and has a distinct life-cycle that defines how the component is created and destroyed. The communication between these components (except Content providers) is done using messages called "Intents" (section 1.1.2). It is also important to note that all of these components needs to be listed in AndroidManifest.xml file, for more detailed description of this file please look at section 1.2.1. There are four different types of app components:

- Activities An activity is the entry point for interacting with the user. It represents a single screen with a user interface. Each activity is independent from others [1].
- Services A service is a general-purpose entry point for keeping an app running in the background for all kinds of reasons. It is a component that runs in the background to perform long-running operations or to perform work for remote processes. A service does not provide a user interface[1].
- Broadcast receivers A broadcast receiver is a component that enables the system to deliver events to the app outside of a regular user flow, allowing the app to respond to system-wide broadcast announcements. Because broadcast receivers are another well-defined entry into the app, the system can deliver broadcasts even to apps that aren't currently running. Although broadcast receivers don't display a user interface, they may create a status bar notification to alert the user when a broadcast event occurs. More commonly, though, a broadcast receiver is just a gateway to other components and is intended to do a very minimal amount of work [1].
- Content providers A content provider manages a shared set of app data that you can store in the file system, in a SQLite database, on the web, or on any other persistent storage location that your app can access.

Through the content provider, other apps can query or modify the data if the content provider allows it. For example, the Android system provides a content provider that manages the user's contact information. As such, any app with the proper permissions can query the content provider, such as ContactsContract.Data, to read and write information about a particular person [1].

1.1.2 Intents messages

Three of the four component typesactivities, services, and broadcast receiversare activated by an asynchronous message called an intent. Intents bind individual components to each other at runtime. You can think of them as the messengers that request an action from other components, whether the component belongs to your app or another [1]. Although intents facilitate communication between components in several ways, there are three fundamental use cases:

- Starting an activity
- Starting a service
- Delivering a broadcast

Readers more interested in this topic are recommend to have a look at [2].

Add ref to section describing the use of am and broadcast to fire activities and intents

1.2 APK file

Android Application Package(APK) is the file format used for an android application. It contains all the resources required for an application to run on android operating system. Its basically a zip file or a jar file with extension of ".apk"[3].

1.2.1 APK file contents

Normally an apk file contains following files or folders:

Add captions and made the picture available in list of figures

• assets/: It provides a way to include arbitrary files like text, xml, fonts, music and video in your application and allow you to access your data raw/untouched. AssetManager is used to read this data[4]. Due to raw access sometimes this directory contains executable payloads and dynamically loaded code. One interesting usage is storing Dex files in it to avoid its reverse engineering. [5]

Figure 1: Files inside an APK

• lib/: This directory is for natively compiled code. This directory contains a subdirectory for each platform type, like armeabi, armeabi-v7a, arm64-v8a, x86, x86_64, and mips [3]. This code is run directly on CPU and have access to android API using Java Native Interface(JNI). Natively compiled code is more suitable for CPU intensive jobs because of less overhead and good performance of programming language like c/c++. Most of the android static analysis tools work on Java level- that is, they process either the decompiled Java source code or Dalvik Byte Code[6]. This rises several interesting scenarios in which malware authors can avoid detection, can redistributing benign applications with malicious injections or completely modifying behavior of an application. Readers interested in this topic are encouraged to have a look at [6]. Android NDK can be used to compile native code for android.

compile hello world in c for android in apendix

- META-INF/: This directory contains the following three files:
 - 1. **MANIFEST.MF:** Its a text file and contains a list and base64 encoded SHA-1 hashes of all files included in the APK.
 - CERT.SF: This file again contain a list of all files but this time with the base64 encoded SHA-1 hashes of the corresponding lines in the MANIFEST.MF file. It also contain based64 encoded SHA-1 hash of MANIFEST.MF file.
 - 3. **CERT.RSA:** It contains developers public signature, used for validation of upgrades. Its basically singed content of CERT.SF file along with public key to validate the contents.
- res/: This directory contain resource which are not compiled into "re-

sources.arsc" (see below) [3]. These resources can be accessed from inside the application code using resource ID. All resource IDs are defined in "R" class of the project. Application developers can specify alternate resources to support specific device configurations e.g, alternative drawable resources for different screen sizes, alternative strings for different languages etc.

- AndroidManifest.xml: Every application must have an AndroidManifest.xml file. This file provide essential information about the application like entry points, package name, components, permissions, minimum level of Android API, libraries, intents etc. For static analysis purposes a lot of information can be extracted from this file.
- classes.dex: This is the most important file insude an apk. It contains classes compiled in the DEX file format which can be understood by the Dalvik/ART virtual machine [3]. In the next section we will describe this file in more details.
- resources.arsc: This file contain compiled resources. This file contains the XML content from all configurations of the res/values/ folder. The packaging tool extracts this XML content, compiles it to binary form, and archives the content. This content includes language strings and styles, as well as paths to content that is not included directly in the resources.arsc file, such as layout files and images [3]. These resources can also be accessed using the "R" class.

1.3 Dex file

Dex file is the heart of an android application. First Java source code of an application is compiled to Java byte code (".class" extension). Then this Java byte code is compiled to Dalvik Byte Code or Dalvik Executable(DEX) using Dex-compiler or dexer tool. This code is then executed on Dalvik Virtual Machine (deprecated) or in case of Android Runtime (ART), this code is compiled at install time to the native code.

1.3.1 Dex file format

In this section we will briefly discuss the file format for dex files. For more in depth and up to date specifications readers are encouraged to have a look at android official documentation on dex format [7]. A more graphical representation of dex file is shown in Figure 2. In 2 we had shown that how one element of proto_ids points to different locations in a dex file with the help of lines.

structure of Dex file

DALVIK EXECUTABL >adb shell dalvikvm -cp /data/hw.zip hw Hello World! **HEADER** size /offset strings ids type ids proto ids field ids method ids class defs data 0 1 2 3 4 5 6 7 8 9 A B C D ### data ### .e .x 0A .0 .3 .5 00 6F 53 89 BC 1E 79 B2 4F 1F 9C 09 66 15 23 2D 3B 56 65 32 C3 B5 81 B4 5A 70 02 00 00 70 00 00 00 78 56 34 12 00 00 00 00 00 00 00 00 DC 01 00 00 0C 00 00 00 70 00 00 00 07 00 00 00 A0 00 00 00 02 00 00 00 BC 00 00 00 050: 01 00 00 00 D4 00 00 00 02 00 00 00 DC 00 00 00 **01 00 00 00 EC 00 00 00 64 01 00 00 0C 01 00 00** 060: 070: A6 01 00 00 3A 01 00 00 8A 01 00 00 40 01 00 00 B4 01 00 00 76 01 00 00 54 01 00 00 6C 01 00 00 080: TYPE IDS 57 01 00 00 70 01 00 00 A1 01 00 00 C8 01 00 00 aAa. 01 00 00 00 02 00 00 00 03 00 00 00 04 00 00 00 05 00 00 00 06 00 00 00 08 00 00 00 07 00 00 00 0B0: PROTO IDS 05 00 00 00 <mark>34 01 00 00</mark> 07 00 00 00 05 00 00 00 FIELD IDS 0E0: 01 00 00 00 02 00 00 00 00 00 00 00 FF FF FF FF METHOD IDS 110: 1A 01 00 00 6E 20 01 00 10 00 0E 00 01 00 00 00 130. 06 00 00 00 01 00 00 00 03 00 04 .L .h 140: 12 .L .j .a .v .a ./ .l .a .n .c .t .; 00 01 .V 00 13 .[.L g ./ .0 .b .j .j .a .v .a ./ CLASS DEFS 160: .a .n .g ./ .S .t .r .i .n .g .; 00 04 .m .a .i .n 00 12 .L .j .a .v .a 00 02 .V .L 00 .a ./ .l .a .n 170: .g ./ .S .y .s .t .e .m .; CODE 190: 1A0: .l .d .! 00 12 .L .j .a .v .a ./ .l .a .n .g 100: .S.t.r.i.n.g.; 00 07 .p.r.i.n.t.l.n 00 00 00 01 00 00 09 8C 02 00 00 00 0C 00 00 00 6 ("[Liava/lang/String:") TYPE LIST 1D0: **00 00 00 00 01 00 00 00** 00 00 00 01 00 00 00 1F0: 9C 99 99 99 79 99 99 99 **92 99 99 97** 99 99 99 A0 00 00 00 **03 00 00 00 02 00 00 00** BC 00 00 00 04 00 00 00 01 00 00 00 D4 00 00 00 05 00 00 00 STRING 220: 02 00 00 00 DC 00 00 00 06 00 00 00 01 00 00 00 EC 00 00 00 01 20 00 00 01 00 00 00 0C 01 00 00 DATA **01 10 00 00 02 00 00 00 2**C 01 00 00 **02 20 00 00** (MUTF-8) OC 00 00 00 3A 01 00 00 00 20 00 00 01 00 00 00 250: D1 01 00 00 00 10 00 00 01 00 00 00 DC 01 00 00 **CLASS DATA ANGE ALBERTINI** count 12 x00000 (HEADER) 1 0x0000 x00001 (STRING) 12 0x070 x00002 (TYPE) 7 0x000 x00003 (PROTO) 2 0x000 x0004 (FIELD) 1 0x000 x0004 (CLASS) 1 0x000 x0001 x0000 0x000 0x000 x0001 0x000 0x000 0x000

Figure 2: Dex file format [8]

MAP

change table to multipage table

Add information about Janus vulnerability to make the reading interesting

Name	Format	Description
header	header_item	The header contain information about how the dex file is organized, sizes of different sections inside the dex file, size of dex file, size of data section, version of dex format etc.
string_ids	list of string_id_items	Its a list of string identifiers. These are identifiers for all the strings used by this file e.g, class names, method names, constant objects. Each item points to a location in data section (see below) where the original string is stored.
type_ids	list of type_id_items	This list contain type identifiers for all types (classes, arrays or primitive types) referred to by this file, whether defined in the file or not. The actual identifier string is stored in data section. Items in this list points to items in string_ids list and which in turn points to type identifier string stored in data section.
$\mathrm{proto_ids}$	list of proto_id_items	Its a method prototype identifier list. Each item of this list contain three elements: • shorty_idx Points to string_id_item of
		 shorty descriptor for this prototype return_type_id Specify return type by pointing to corresponding type_id _item
		• parameter_off Offset from start of file to the list of parameter types for this prototype. It must point to location in data section. The data there should be in "type_list" format. This value would be zero in case no parameters.
field_ids	list of field_id_items	These are identifiers for all fields referred to by this file, whether defined in the file or not.
method_ids	list of method_id_items	These are identifiers for all methods referred to by this file, whether defined in the file or not.
class_defs	list of class_def_items	The classes must be ordered such that a given class's superclass and implemented interfaces appear in the list earlier than the referring class. Furthermore, it is invalid for a definition for the same-named class to appear more than once in the list.
call_site_ids	list of call_site_id_items	These are identifiers for all call sites referred to by this file, whether defined in the file or not.
method_handles	list of method_handle_items	A list of all method handles referred to by this file, whether defined in the file or not. This list is not sorted and may contain duplicates which will logically correspond to different method handle instances.

1.3.2 Multiple Dex files in single APK

Android app (APK) files contain executable bytecode files in the form of Dalvik Executable (DEX) files, which contain the compiled code used to run your app. The Dalvik Executable specification limits the total number of methods that can be referenced within a single DEX file to 65,536 including Android framework methods, library methods, and methods in your own code. This limit is referred to as the '64K reference limit'

Cite https://developer.android.com/studio/build/multidex.html

. [9]

Versions of the platform prior to Android 5.0 (API level 21) use the Dalvik runtime for executing app code. By default, Dalvik limits apps to a single classes.dex bytecode file per APK.Multidex support library can be used to workaround this limitation. Android 5.0 (API level 21) and higher uses a runtime called ART which natively supports loading multiple DEX files from APK files

Cite https://developer.android.com/studio/build/multidex.html

. Because of this support its not uncommon these days to come across APKs that contain multiple dex files e.g, Facebook, instagram etc. [9]

1.4 Android Application Analysis

TODO: Write introduction section after the significant part of report is done and the structure is more clear

To be done later, In this chapter we include the problem statement, See fh kiel project report structure for missing parts.

2 Static Analysis

There are several static analysis tools available for APKs, each one having its own strengths and weaknesses.

Add info from http://orbilu.uni.lu/bitstream/10993/26879/1/tr_slr_article.pdf

Add some info about common tools

- 2.1 Smali/Backsmali
- 2.2 IDA pro
- 2.3 JADX Dex to Java decompiler
- 2.4 Apktool

APKTool is one of the major reverse engineering tools for android applications.

Add more info

2.5 Androguard

Introduce androguard

MalloDroid, extension of androguard https://www.dfn-cert.de/dokumente/workshop/2013/FolienSmith.pdf

Androguard used in http://lilicoding.github.io/SA3Repo/papers/2013_guo2013characterizing.pdf

Androguard is an open source tool written in python for analyzing android applications. Its been used in several tools including Virustotal and Cuckoodroid among others. It can process APK files, dex files or odex files. It can disassemble Dex/Odex files to small code and can decompile Dex/Odex to Java code. Being python based and open source it allows for automating most the analysis process and one can make desired improvements.

Androguard doesn't have a lot of documentation available online and most of the time one has to figure it out from source code of androguard. For easier understanding and use, we can generalize the classes androgaurd contain into two groups. Table

2.6 Dex2Jar and jd-gui

TODO: Do androguard basic usage examples

Discuss the changes we made including normalization, canonical hasing for similarity search

Fix the position of table

Classes for Parsing

- APK Used for accessing all elements inside an APK, including information from Manifest.xml like permissions, activities etc.
- DalvikVMFormat It parses the dex file and gives access classes, methods, strings etc. defined inside the dex file.
- ClassDefItem Class for interacting with class information inside the dex file.
- EncodedMethod Class for interacting with method information inside the dex file.
- Instuction Class for interacting with instructions, it contains mnem, opcodes etc. Its a base class and a androguard derive a class for each instruction format from this class.

Classes for Analysis

- Analysis Its the main analysis class and contain instances of all other analysis classes discussed below. create_xref() method needs to be called after an instance of this class is created to populate all defined fields in this class.
- ClassAnalysis This class contain analysis data of a class like cross references and external methods etc.
- MethodAnalysis Contain analysis information of a method like the basic blocks it is composed of etc.
- DvmBasicBlock Represents a simple basic block of a method. It contains information about that basic block like its parents, children etc.

Table 1: Some classes of androguard and their description

Discuss the info we are extracting from apks for platform

TODO: Do androguard comparison apks to see how many functions has added and how many removed, make a table out of it

TODO: Find reused code section in sonicspy or bankbots or lokibot

Usage of androguard for extracting features for AI/ML, prepare for talk in AIOLI-FFM group

Ask lukas for some results from platform

Improvements in androguard

3 Dynamic Analysis: Cuckoo-droid based on Cuckoo sandbox

Introduction to cuckoodroid				
Fixing cuckoodroid				
Persistent root problem				
Lates android				
python compilation workaround, termux				
Slow android emulator				

4 Dynamic Analysis: Anti-Emulator Detection

Common methods employed for emulator detection, some literature

Good and bad uses of anti-emulator detection

Testing results of cuckoodroid against common emulator detection methods

Adding some new anti-emulator detection features to cuckoodroid

result of analysis before and after
